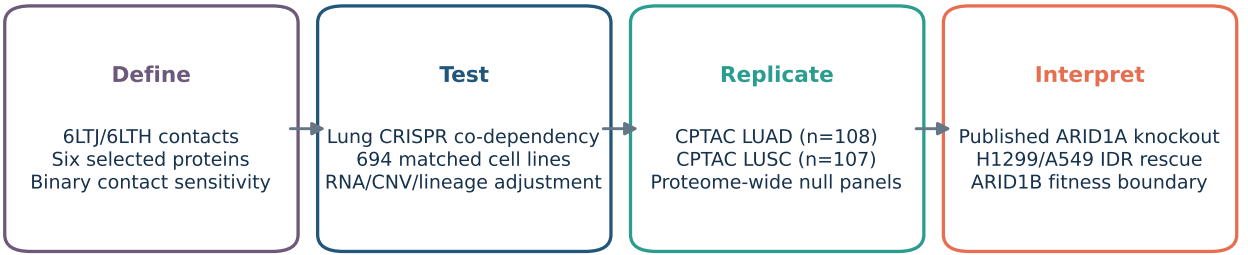
Focused biological question

Does a structure-selected cBAF panel show reproducible residual protein co-variation in lung cancer?



ARID1A state is not interchangeable

Alteration: any annotated variant
Predicted loss of function: truncating/splice variant
Engineered loss: verified knockout
Protein-low: abundance proxy only

Inference boundary

Residual co-variation is not a direct-contact effect
Co-dependency is not loss-conditioned lethality
ARID1B support does not imply whole-cBAF dependence
No therapeutic marker is claimed

Primary endpoint: selected-panel minus broad-BAF-background median correlation of linear-model residuals.
